Contents

1	The Axiom Compiler	1
1.1	Makefile	1
2	Overview	3
2.1	Syntax by Jacob Smith	4
2.1.1	Language features	13
2.1.2	Semantics	13
2.2	The Input	15
2.3	The Output, the EQ.nrlib directory	19
2.4	The code.lsp and EQ.lsp files	20
2.5	The code.o file	33
2.6	The info file	33
2.7	The EQ.fn file	36
2.8	The index.kaf file	40
2.8.1	The index offset byte	41
2.8.2	The “loadTimeStuff”	42
2.8.3	The “compilerInfo”	44
2.8.4	The “constructorForm”	50
2.8.5	The “constructorKind”	50
2.8.6	The “constructorModemap”	50
2.8.7	The “constructorCategory”	52
2.8.8	The “sourceFile”	53
2.8.9	The “modemaps”	53
2.8.10	The “operationAlist”	55
2.8.11	The “superDomain”	56

2.8.12	The “signaturesAndLocals”	56
2.8.13	The “attributes”	57
2.8.14	The “predicates”	57
2.8.15	The “abbreviation”	58
2.8.16	The “parents”	58
2.8.17	The “ancestors”	58
2.8.18	The “documentation”	59
2.8.19	The “slotInfo”	60
2.8.20	The “index”	62
3	Compiler top level	63
3.1	Spad Program Representation	63
3.2	Global Data Structures	64
3.3	Pratt Parsing	64
3.4)compile	65
3.4.1	Spad compiler	66
3.5	Operator Precedence Table Initialization	67
3.5.1	LED and NUD Tables	68
3.6	Glyph Table	70
3.6.1	Rename Token Table	71
3.6.2	Generic function table	71
3.7	Giant steps, Baby steps	71
4	The Parser	73
4.1	EQ.spad	73
4.2	boot transformations	77
4.2.1	defun string2BootTree	77
4.2.2	defun new2OldLisp	78
4.2.3	defun new2OldTran	78
4.2.4	defun newIf2Cond	79
4.2.5	defun newDef2Def	79
4.2.6	defun new2OldDefForm	79
4.2.7	defun newConstruct	80
4.3	preparse	80

4.3.1	defvar \$index	80
4.3.2	defvar \$linelist	80
4.3.3	defvar \$echolinestack	81
4.3.4	defvar \$preparse-last-line	81
4.4	Parsing routines	81
4.4.1	defun initialize-preparse	81
4.4.2	defun preparse	85
4.4.3	defun Build the lines from the input for piles	85
4.4.4	defun skip-ifblock	90
4.4.5	defun preparseReadLine1	91
4.4.6	defun expand-tabs	92
4.5	I/O Handling	93
4.5.1	defun preparse-echo	93
4.5.2	Parsing stack	93
4.5.3	defstruct stack	93
4.5.4	defun stack-load	93
4.5.5	defun stack-clear	94
4.5.6	defmacro stack-/-empty	94
4.5.7	defun stack-push	94
4.5.8	defun stack-pop	94
4.5.9	Parsing token	95
4.5.10	defstruct token	95
4.5.11	defvar prior-token	95
4.5.12	defvar nonblank	95
4.5.13	defvar current-token	95
4.5.14	defvar next-token	96
4.5.15	defvar valid-tokens	96
4.5.16	defun token-install	96
4.5.17	defun token-print	96
4.5.18	Parsing reduction	97
4.5.19	defstruct reduction	97

New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

The Axiom Compiler

1.1 Makefile

a : b \rightarrow This book is actually a literate program[Knut92] and contains executable source code. In particular, the Makefile for this book is part of the source of the book and is included below.

Chapter 2

Overview

The Spad language is a mathematically oriented language intended for writing computational mathematics. It derives its logical structure from abstract algebra. It features ideas that are still not available in general purpose programming languages, such as selecting overloaded procedures based on the return type as well as the types of the arguments.

The Spad language is heavily influenced by Barbara Liskov's work. It features encapsulation (aka objects), inheritance, and overloading. It has categories which are defined by the exports. Categories are parameterized functors that take arguments which define their behavior.

More details on the language and its high level concepts is available in the Programmers Guide, Volume 3.

The Spad compiler accepts the Spad language and generates a set of files used by the interpreter, detailed in Volume 5.

The compiler does not produce stand-alone executable code. It assumes that it will run inside the interpreter and that the code it generates will be loaded into the interpreter.

Some of the routines are common to both the compiler and the interpreter. Where this happens we have favored the interpreter volume (Volume 5) as the official source location. In each case we will make reference to that volume and the code in it. Thus, the compiler volume should be considered as an extension of the interpreter document.

This volume will go into painful detail of every aspect of compiling Spad code. We will start by defining the input to, and output from the compiler so we know what we are trying to achieve.

Next we will look at the top level data structures used by the compiler. Unfortunately, the compiler uses a large number of "global variables" to pass information and alter control flow. Some of these are used by many routines and some of these are very local to a small subset or a recursion. We will cover the minor ones as they arise.

Next we examine the Pratt parser idea and the Led and Nud concepts, which is used to drive the low level parsing.

Following that we journey deep into the code, trying our best not to get lost in the details. The code is introduced based on "motivation" rather than in strict execution order or related concept order. We do this to try to make the compiler a "readable novel" rather than a mud-

march through the code. The goal is to keep the reader’s interest while trying to be exact. Sometimes this will require detours to discuss subtopics.

“Motivating” a piece of software is a not-very-well established form of narrative writing so we assume your forgiveness if we get it wrong. Worse yet, some of the pieces of the system are “legacy”, in that they are no longer used and should be removed. Other parts of the system may have very weak descriptions because we simply do not understand them either. Since this is a living document and the code for the system is actually the code you are reading we will expand parts as we go.

where $Z^?$ represents an optional Z , Z^+ a non-empty finite sequence of Z , the square brackets are used for grouping.

ToplevelDef A toplevel definition is either a Spad category definition, or a Spad domain definition, or a Spad package definition, or a delayed definition.

CategoryDef A Spad category definition specifies a class of algebras, by declaring the sig-

natures of the required operations. A Spad category definition may extend existing Spad categories with new signatures. For example, the fragment

```
Monoid(): Category == with
  *: (%,% ) -> %
  1: %
```

declares `Monoid` as a Spad category with two signatures:

1. the symbol `*` is a binary operation on the domain belonging to this category
2. the identifier `1` denotes a constant object of a domain belonging to the category being defined.

The following category definition

```
Group(): Category == Monoid with
  inverse: % -> %
```

extends `Monoid` with the `inverse` operation, to capture the mathematical notion of group structure. One can think of Spad categories as *specifying* views on objects.

Exports Definitions for Spad categories, Spad domains, and packages specify exported operations, i.e., the “public interface” in programming languages jargon, through either a *WithExpr*, or an *Extension*, or a combination of both.

WithExpr A *WithExpr* is essentially an unnamed Spad category consisting of a list of operations with signatures (*Signature*).

Extension Definitions for Spad categories and Spad domains may extend existing Spad categories or domains. An extension may specify either a type, or multiple categories through the `Join` operator. The latter form corresponds to multiple inheritance in object-oriented programming languages.

Signature The specification of a type for an identifier can appear in a *WithExpr*, as a parameter declaration in *CallForm*, as a field of a record or union, or in a local variable definition.

Type A type is a built-in type (`Boolean`, `Integer`, `Float`), a record or union, a function type, the name of a Spad category or Spad domain, or an instantiation of a Spad category or Spad domain. All field names specified by signatures in a record must be distinct. Similarly, all field names specified in a union must be distinct and unique in the enclosing scope; this applies recursively to any other union types directly referenced in the signature list of the union.

DomainDef A Spad domain definition provides implementations for views specified by categories. A domain definition has an interface specification part (*Exports*) stating the categories and possible additional signatures it implements, and an implementation part called *capsule*. The implementation part may define the representation of the object belonging to the domain, and provide definitions for operations declared in its *Exports*. For example, the program fragment

```
IntMonoid(): Monoid == add
  Rep == Integer
  (x:% ) * (y:% ) == (rep x + rep y)$Integer
  1:% == 0::Integer
```

provides an implementation of `IntMonoid` for the `Monoid` specification as follows:

- the object representation domain is `Integer`;

- “multiplication” of two objects in `IntMonoid` is the value obtained by adding their respective underlying values (returned by the `*` operator);
- the `Integer` constant 0 is the underlying value of the unit of `IntMonoid`

Note that a Spad domain almost always references the “current domain” using the symbol `%`.

PackageDef A package definition provides implementations for functions that operate on a Spad domain. Unlike a Spad domain, a package does not define a *Representation* and does not reference the symbol `%`. Like a Spad domain, it has an *Exports* part and an implementation part.

Capsule The implementation part of a Spad domain or package is its capsule. A capsule may specify the representation of a domain (if it is the implementation of a domain), and specifies a sequence of toplevel definitions for operations on the Spad domain objects, or the operators in a package.

sl Representation A Spad domain specifies the underlying representation of its objects by assigning a type expression to the identifier `Rep`. A *Representation* can occur only in a Spad domain definition.

Definition A (delayed) definition is the binding of an identifier or a function call expression to a Spad category, Spad domain, or an ordinary function. The body of the definition is evaluated when needed. That evaluation may happen only once for a given argument list. Even though the evaluation is delayed, the body is still fully type checked at the definition point. The Spad language, as understood by the Spad compiler, does not allow ordinary function definitions at the toplevel. However, they are the core of the language understood by the interpreter. For uniformity, we include toplevel function definitions in the Spad subset we describe.

CallForm A call form consists of an identifier and a parenthesized sequence of signatures declaring formal parameters. A call form is needed in the definitions of a Spad category, Spad domain, and function.

Statement Statements appear in the body of function definitions. A statement is either an expression, a one or two-arm if-statement, an iteration where the body of the iteration (a statement) is controlled by a list of iterators, a local variable definition, or an assignment.

Iterator An iterator is either a sequence of items x drawn from a sequence e , possibly filtered by a predicate p , or a repeated evaluation of a predicate.

Expression An expression is either a constant, variable, function call, member selection, type-case expression, an assignment, or a qualified expression. A qualified expression is an expression that contains free variables and is immediately followed by their definitions in a where-clause. We assimilate expressions built with built-in operations – such as addition on integers, etc. – as function calls.

Variable A variable is the use of a name declared with a given type

Constant A constant is a built-in value, such as $+^{Integer \times Integer \rightarrow Integer}$, $345^{Integer}$, $true^{Boolean}$, etc.

Identifier An identifier is a finite sequence of characters. The set of identifiers in Spad is countably infinite.

2.1.1 Language features

The Spad programming language supports elements of dependent types, a result of the functorial nature of the data-structuring mechanisms available in Spad. That is, the Spad type system allows types to be function-like objects with arguments that depend on types and values. Dependent types enables an unusually direct style of implementation of mathematical structures.

The Spad programming language also supports general function overloading; in particular, a function can be overloaded on its argument and return types. The overload resolution algorithm exploits all context information, including arguments and target types, to select the best matching function. Implicit conversion is supported through the `coerce` operator.

2.1.2 Semantics

The computational rules used to evaluate Spad programs are those of *eager* semantics (and call-by-value), and the arguments of functions are passed by reference. We sketch the semantics of Spad programs in two ways: small-step operational semantics, and denotational semantics. The small-step operational semantics gives an intuitive idea of the behavior of Spad programs, whereas the denotational semantics lets us associate mathematical functions to Spad programs. The latter allows us to formally talk about the notion of a derivative of a Spad program.

Operational semantics

The Spad language is imperative in the sense that its programs operate on stores by explicit modification. Values of Spad programs can be booleans, integers, floating point numbers, aggregates thereof, or function codes. We denote the collection of values by **Value**, inductively defined as:

- Location values: object locations are in **Value**
- Boolean values: **true** \in **Value** and **false** \in **Value**
- Integer Values: integer constants $n^{Integer}$ are in **Value**
- Float values: float constants f^{Float} are in **Value**
- Functions: If f is a defined function of type $\tau_1 \rightarrow \tau_2$
then the constant $f^{\tau_1 \rightarrow \tau_2}$ is in **Value**
- Aggregates: if $c_i^{\tau_i}$ are values of type τ_i in **Value**,
then the tuple $(c_1^{\tau_1}, \dots, c_n^{\tau_n})^{\tau_1 \times \dots \times \tau_n}$ is in **Value**.
Tuples represent record values.
Similarly, if c^{τ_1} is in **Value**, so is $c^{\tau_2 \leftarrow \tau_1}$.
It represents a value of a field of type τ_1 in a union τ_2 .

The behavior of a Spad program is a sequence of configurations $\langle p, \sigma, \Gamma \rangle$ where p denotes fragments of Spad constructs, σ the store of values, and Γ the current environment of bindings of variables to types and expressions. The notation $\Gamma, x^\tau == e$ denotes an environment obtained by extending Γ with the binding $x^\tau == e$. The $== e$ part may be missing. A store of σ is a mapping from memory locations to Spad values. We use the notation $\sigma[v/l]$ to designate an *updated function* defined by

$$\sigma[v/l] = \begin{cases} v & \text{if } x = l \\ \sigma(x) & \text{otherwise} \end{cases}$$

Each configuration is defined by structural induction on the syntax of Spad.

Denotational semantics

The basic idea of algorithmic differentiation rests on the notion that a computer program computes a function whose range has a ring structure; and the collection of such functions can be endowed with a *differential algebra* structure. The theory of *denotational semantics* is a useful tool. We see a standard denotational semantics of the Spad programming language that respects the operational semantics outlined above, i.e.

$$t \rightarrow^* v^\tau \Rightarrow [[t]] = [[v^\tau]]$$

Variable

$$\langle x^\tau, \sigma, \Gamma \rangle \rightarrow \langle \sigma(x^\tau), \sigma, \Gamma \rangle$$

Call-Arguments

$$\frac{\langle e_i, \sigma, \Gamma \rangle \rightarrow \langle e'_i, \sigma', \Gamma \rangle}{e_0(v_1, \dots, e_i, \dots, e_n), \sigma, \Gamma \rightarrow \langle e_0(v_1, \dots, e'_i, \dots, e_n), \sigma', \Gamma \rangle}$$

where the x_i are parameters of v_0

Call-Operator

$$\frac{\langle e_0, \sigma, \Gamma \rangle \rightarrow \langle e_0, \sigma', \Gamma \rangle}{\langle e_0(v_1, \dots, v_n), \sigma, \Gamma \rangle \rightarrow \langle e'_0(v_1, \dots, v_n), \sigma', \Gamma \rangle}$$

where the x_i are the parameters of v_0

Call

$$\langle v_0^{\tau_0}(v_1^{\tau_1}, \dots, v_n^{\tau_n}), \sigma, \Gamma \rangle \rightarrow \langle v_0^{\tau_0}[v_1^{\tau_1}/x_1, \dots, v_n^{\tau_n}/x_n], \sigma, \Gamma \rangle$$

where the x_i are parameters of v_0

Qualified Expression

$$\frac{\dots \quad \langle \delta_1, \sigma, \Gamma_1 \rangle \rightarrow \langle \delta'_1, \sigma, \Gamma_2 \rangle \quad \langle \delta_2, \sigma, \Gamma_2 \rangle \rightarrow \langle \delta'_2, \sigma, \Gamma_3 \rangle \quad \dots \quad \langle \delta_n, \sigma, \Gamma_n \rangle \rightarrow \langle \delta'_n, \sigma, \Gamma_{n+1} \rangle \quad \langle e, \sigma, \Gamma_{n+1} \rangle \rightarrow \langle e', \sigma', \Gamma_{n+2} \rangle}{\langle e \text{ where } \delta_1 \dots \delta_n, \sigma, \Gamma_1 \rangle \rightarrow \langle e', \sigma', \Gamma_{n+2} \rangle}$$

Sequence-Head

$$\frac{\langle s_1, \sigma_1, \Gamma_1 \rangle \rightarrow \langle s'_1, \sigma_2, \Gamma_2 \rangle}{\langle s_1; s_2, \sigma_1, \Gamma_1 \rangle \rightarrow \langle s'_1; s_2, \sigma_2, \Gamma_2 \rangle}$$

Sequence-Tail

$$\langle v_1; s_2, \sigma, \Gamma \rangle \rightarrow \langle s_2, \sigma, \Gamma \rangle$$

If-True

$$\frac{\langle s_1, \sigma, \Gamma \rangle \rightarrow \langle s'_1, \sigma', \Gamma' \rangle}{\langle \text{if true then } s_1; s_2, \sigma, \Gamma \rangle \rightarrow \langle s'_1, \sigma', \Gamma' \rangle}$$

If-False

$$\frac{\langle s_2, \sigma, \Gamma \rangle \rightarrow \langle s'_2, \sigma', \Gamma' \rangle}{\langle \text{if false then } s_1; s_2, \sigma, \Gamma \rangle \rightarrow \langle s'_2, \sigma', \Gamma' \rangle}$$

Assignment-Left

$$\frac{\langle e_1, \sigma_0, \Gamma \rangle \rightarrow \langle e'_1, \sigma_1, \Gamma \rangle}{\langle e_1 := e_2, \sigma, \Gamma \rangle \rightarrow \langle e'_1 := e_2, \sigma_1, \Gamma \rangle}$$

Assignment-Right

$$\frac{\langle e_2, \sigma, \Gamma \rangle \rightarrow \langle e'_2, \sigma', \Gamma \rangle}{\langle l := e_2, \sigma, \Gamma \rangle \rightarrow \langle l := e'_2, \sigma', \Gamma \rangle}$$

Assignment

$$\frac{}{\langle l := v^\tau, \sigma, \Gamma \rangle \rightarrow \langle v^\tau, \sigma[v^\tau/l], \Gamma \rangle}$$

Immediate Definition

$$\frac{\langle e, \sigma, \Gamma \rangle \rightarrow \langle e', \sigma_1, \Gamma \rangle}{\langle x : \tau := e, \sigma, \Gamma \rangle \rightarrow \langle x : \tau := e', \sigma_1, \Gamma \rangle}$$

Immediate Definition

$$\langle x : \tau := v^\tau, \sigma, \Gamma \rangle \rightarrow \langle v^\tau, \sigma, \Gamma, x^\tau == v^\tau \rangle$$

2.2 The Input

```

)abbrev domain EQ Equation
--FOR THE BENEFIT OF LIBAXO GENERATION
++ Author: Stephen M. Watt, enhancements by Johannes Grabmeier

++ Description:
++ Equations as mathematical objects. All properties of the basis domain,
++ e.g. being an abelian group are carried over the equation domain, by
++ performing the structural operations on the left and on the
++ right hand side.
-- The interpreter translates "=" to "equation". Otherwise, it will
-- find a modemap for "=" in the domain of the arguments.

Equation(S: Type): public == private where
  Ex ==> OutputForm
  public ==> Type with
    "=": (S, S) -> $

```

```

    ++ a=b creates an equation.
equation: (S, S) -> $
    ++ equation(a,b) creates an equation.
swap: $ -> $
    ++ swap(eq) interchanges left and right hand side of equation eq.
lhs: $ -> S
    ++ lhs(eqn) returns the left hand side of equation eqn.
rhs: $ -> S
    ++ rhs(eqn) returns the right hand side of equation eqn.
map: (S -> S, $) -> $
    ++ map(f,eqn) constructs a new equation by applying f to both
    ++ sides of eqn.
if S has InnerEvalable(Symbol,S) then
    InnerEvalable(Symbol,S)
if S has SetCategory then
    SetCategory
    CoercibleTo Boolean
    if S has Evalable(S) then
        eval: ($, $) -> $
            ++ eval(eqn, x=f) replaces x by f in equation eqn.
        eval: ($, List $) -> $
            ++ eval(eqn, [x1=v1, ... xn=vn]) replaces xi by vi in equation eqn.
if S has AbelianSemiGroup then
    AbelianSemiGroup
    "+": (S, $) -> $
        ++ x+eqn produces a new equation by adding x to both sides of
        ++ equation eqn.
    "+": ($, S) -> $
        ++ eqn+x produces a new equation by adding x to both sides of
        ++ equation eqn.
if S has AbelianGroup then
    AbelianGroup
    leftZero : $ -> $
        ++ leftZero(eq) subtracts the left hand side.
    rightZero : $ -> $
        ++ rightZero(eq) subtracts the right hand side.
    "-": (S, $) -> $
        ++ x-eqn produces a new equation by subtracting both sides of
        ++ equation eqn from x.
    "-": ($, S) -> $
        ++ eqn-x produces a new equation by subtracting x from
        ++ both sides of equation eqn.
if S has SemiGroup then
    SemiGroup

2.3 The Output, the EQ.nrlib directory

The Spad compiler generates several files in a directory named after the input abbreviation. The input file contains an abbreviation line:

```
)abbrev domain EQ Equation
```

for each category, domain, or package. The abbreviation line has 3 parts.

- one of “category”, “domain”, or “package”
- the abbreviation for this domain (8 Uppercase Characters maximum)
- the name of this domain

Since the abbreviation for the Equation domain is EQ, the compiler will put all of its output into a subdirectory called “EQ.nrlib”. The “nrlib” is a port of a very old VMLisp file format, simulated with directories.

For the EQ input file, the compiler will create the following output files, each of which we will explain in detail below.

```

/research/test/int/algebra/EQ.nrlib:

2.5 The code.o file

The Spad compiler translates the Spad language into Common Lisp. It eventually invokes the Common Lisp “compile-file” command to output files in binary. Depending on the lisp system this filename can vary (e.g “code.fasl”). The details of how these are used depends on the Common Lisp in use.

By default, Axiom uses Gnu Common Lisp (GCL), which generates “.o” files.

2.8 The index.kaf file

Each constructor (e.g. EQ) had one library directory (e.g. EQ.nrlib). This directory contained a random access file called the index.kaf file. These files contain runtime information such as the operationAlist and the ConstructorModemap. At system build time we merge all of these .nrlib/index.kaf files into one database, INTERP.daase. Requests to get information from this database are cached so that multiple references do not cause additional disk i/o.

Before getting into the contents, we need to understand the format of an index.kaf file. The kaf file is a random access file, originally used as a database. In the current system we make a pass to combine these files at build time to construct the various daase files.

This is just a file of lisp objects, one after another, in (read) format.

A kaf file starts with an integer, in this case, 35695. This integer gives the byte offset to the index. Due to the way the file is constructed, the index is at the end of the file. To read a kaf file, first read the integer, then seek to that location in the file, and do a (read). This will return the index, in this case:

```
((("slot1Info" 0 32444)
  ("documentation" 0 29640)
  ("ancestors" 0 28691)
  ("parents" 0 28077)
  ("abbreviation" 0 28074)
  ("predicates" 0 25442)
  ("attributes" 0 25304)
  ("signaturesAndLocals" 0 23933)
  ("superDomain" 0 NIL)
  ("operationAlist" 0 20053)
  ("modemaps" 0 17216)
  ("sourceFile" 0 17179)
  ("constructorCategory" 0 15220)
  ("constructorModemap" 0 13215)
  ("constructorKind" 0 13206)
  ("constructorForm" 0 13191)
  ("compilerInfo" 0 4433)
  ("loadTimeStuff" 0 20))
```

This is a list of triples. The first item in each triple is a string that is used as a lookup key (e.g. “operationAlist”). The second element is no longer used. The third element is the byte offset from the beginning of the file.

So to read the “operationAlist” from this file you would:

1. open the index.kaf file
2. (read) the integer
3. (seek) to the integer offset from the beginning of the file
4. (read) the index of triples
5. find the keyword (e.g. “operationAlist”) triple
6. select the third element, an integer
7. (seek) to the integer offset from the beginning of the file
8. (read) the “operationAlist”

Note that the information below has been reformatted to fit this document. In order to save space the index.kaf file is does not use prettyprint since it is normally only read by machine.

2.8.1 The index offset byte

35695

Compiler top level

3.1 Spad Program Representation

From Davenport[[Dave84a](#)] and Dos Reis et al.[[Dosr11](#)]

The Spad programming language is strongly typed. Yet, it allows for runtime instantiation of domains and categories. Consequently, categories and domains are both compile-time and runtime objects. From now on, we will discuss only the representation of category objects. Domains and packages are similarly represented, with some variations to attend to data specific to domains.

0	CategoryForm	
1	ExportInfoList	
2	AttributeList	
3	(Category)	
4	0	PrincipalAncestorList
	1	ExtendedCategoryList
	2	DomainInfoList
5	UsedDomainList	
⋮	vdots	

Figure: Layout of category objects

A category object is represented as a large heterogeneous tuple as shown in the figure above. Its components have the following meaning:

- slot 0 holds the canonical category form of the expression whose evaluation produces the category object under consideration.
- slot 1 holds a list of function signatures exported by the category
- slot 2 holds a list of attributes and the condition under which they hold
- slot 3 always contains the form '(category)'. It serves as a runtime type checking tag
- slot 4 contains 3 parts:
 - a list of principal ancestor category forms
 - a list of directly extended category forms

- a list of domains explicitly used in that category
- slot 5 holds the list of all domain forms mentioned in the exported signatures
- each of the slots 6 and onwards holds either runtime information about a specific exported signature, or a pointer to a domain object or a category object.

3.2 Global Data Structures

3.3 Pratt Parsing

Parsing involves understanding the association of symbols and operators. Vaughn Pratt [Prat73] poses the question “Given a substring AEB where A takes a right argument, B a left, and E is an expression, does E associate with A or B?”.

Floyd [Floy63] associates a precedence with operators, storing them in a table, called “binding powers”. The expression E would associate with the argument position having the highest binding power. This leads to a large set of numbers, one for every situation.

Pratt assigns data types to “classes” and then creates a total order on the classes. He lists, in ascending order, Outcomes, Booleans, Graphs (trees, lists, etc), Strings, Algebraics (e.g. Integer, complex numbers, polynomials, real arrays) and references (e.g. the left hand side of assignments). Thus, Strings \leq References. The key restriction is “that the class of the type at any argument that might participate in an association problem not be less than the class of the data type of the result of the function taking that argument”.

For a less-than comparison (“ $<$ ”) the argument types are Algebraics but the result type is Boolean. Since Algebraics are greater than Boolean we can associate the Algebraics together and apply them as arguments to the Boolean.

In more detail, there an “association” is a function of 4 types:

- a_A – The data type of the right argument
- r_A – The return type of the right argument
- a_B – The data type of the left argument
- r_B – The return type of the left argument

Note that the return types might depend on the type of the expression E. If all 4 are of the same class then the association is to the left.

Using these ideas and given the restriction above, Pratt proves that every association problem has at most one solution consistent with the data types of the associated operators.

Pratt proves that there exists an assignment of integers to the argument positions of each token in the language such that the correct association, if any, is always in the direction of the argument position with the larger number, with ties being broken to the left.

To construct the proper numbers, first assign even integers to the data type classes. Then to each argument position assign an integer lying strictly (where possible) between the integers corresponding to the classes of the argument and result types.

For tokens like “and”, “or”, +, *, and the Booleans and Algebraics can be subdivided into pseudo-classes so that

terms $<$ factors $<$ primaries

Then `+` is defined over terms, `*` over factors, and `over` primaries with coercions allowed from primaries to factors to terms. To be consistent with Algol, the primaries should be a right associative class (e.g. `xyz`)

3.4)compile

This is the implementation of the `)compile` command.

You use this command to invoke the new Axiom library compiler or the old Axiom system compiler. The `)compile` system command is actually a combination of Axiom processing and a call to the Aldor compiler. It is performing double-duty, acting as a front-end to both the Aldor compiler and the old Axiom system compiler. (The old Axiom system compiler was written in Lisp and was an integral part of the Axiom environment. The Aldor compiler is written in C and executed by the operating system when called from within Axiom.)

User Level Required: compiler

Command Syntax:

```

)compile
)compile fileName
)compile fileName.spad
)compile directory/fileName.spad
)compile fileName )old
)compile fileName )translate
)compile fileName )quiet
)compile fileName )noquiet
)compile fileName )moreargs
)compile fileName )onlyargs
)compile fileName )break
)compile fileName )nobreak
)compile fileName )library
)compile fileName )nolibrary
)compile fileName )vartrace
)compile fileName )constructor nameOrAbbrev

```

Command Description:

The first thing `)compile` does is look for a source code filename among its arguments. Thus

```

)compile mycode.spad
)compile /u/jones/mycode.spad
)compile mycode

```

all invoke `)compiler` on the file `/u/jones/mycode.spad` if the current Axiom working directory is `/u/jones`. (Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started Axiom.)

If you omit the file extension, the command looks to see if you have specified the `)new` or

`)old` option. If you have given one of these options, the corresponding compiler is used.

The command first looks in the standard system directories for files with extension `.as`, `.ao` and `.al` and then files with extension `.spad`. The first file found has the appropriate compiler invoked on it. If the command cannot find a matching file, an error message is displayed and the command terminates.

The first thing `)compile` does is look for a source code filename among its arguments. Thus

```
)compile mycode
)co mycode
)co mycode.spad
```

all invoke `)compiler` on the file `/u/jones/mycode.spad` if the current Axiom working directory is `/u/jones`. Recall that you can set the working directory via the `)cd` command. If you don't set it explicitly, it is the directory from which you started Axiom.

This is frequently all you need to compile your file.

This simple command:

1. Invokes the Spad compiler and produces Lisp output.
2. Calls the Lisp compiler if the compilation was successful.
3. Uses the `)library` command to tell Axiom about the contents of your compiled file and arrange to have those contents loaded on demand.

Should you not want the `)library` command automatically invoked, call `)compile` with the `)nolibrary` option. For example,

```
)compile mycode )nolibrary
```

By default, the `)library` system command *exposes* all domains and categories it processes. This means that the Axiom interpreter will consider those domains and categories when it is trying to resolve a reference to a function. Sometimes domains and categories should not be exposed. For example, a domain may just be used privately by another domain and may not be meant for top-level use. The `)library` command should still be used, though, so that the code will be loaded on demand. In this case, you should use the `)nolibrary` option on `)compile` and the `)noexpose` option in the `)library` command. For example,

```
)compile mycode )nolibrary
)library mycode )noexpose
```

Once you have established your own collection of compiled code, you may find it handy to use the `)dir` option on the `)library` command. This causes `)library` to process all compiled code in the specified directory. For example,

```
)library )dir /u/jones/quantum
```

You must give an explicit directory after `)dir`, even if you want all compiled code in the current working directory processed, e.g.

```
)library )dir .
```

3.4.1 Spad compiler

This command compiles files with file extension `.spad` with the Spad system compiler.

The `)translate` option is used to invoke a special version of the old system compiler that will translate a `.spad` file to a `.as` file. That is, the `.spad` file will be parsed and analyzed and

a file using the new syntax will be created.

By default, the *.as* file is created in the same directory as the *.spad* file. If that directory is not writable, the current directory is used. If the current directory is not writable, an error message is given and the command terminates. Note that `)translate` implies the `)old` option so the file extension can safely be omitted. If `)translate` is given, all other options are ignored. Please be aware that the translation is not necessarily one hundred percent complete or correct. You should attempt to compile the output with the Aldor compiler and make any necessary corrections.

You can compile category, domain, and package constructors contained in files with file extension *.spad*. You can compile individual constructors or every constructor in a file.

The full filename is remembered between invocations of this command and `)edit` commands. The sequence of commands

```
)compile matrix.spad
)edit
)compile
```

will call the compiler, edit, and then call the compiler again on the file **matrix.spad**. If you do not specify a *directory*, the working current directory is searched for the file. If the file is not found, the standard system directories are searched.

If you do not give any options, all constructors within a file are compiled. Each constructor should have an `)abbreviation` command in the file in which it is defined. We suggest that you place the `)abbreviation` commands at the top of the file in the order in which the constructors are defined.

The `)library` option causes directories containing the compiled code for each constructor to be created in the working current directory. The name of such a directory consists of the constructor abbreviation and the **.nrlib** file extension. For example, the directory containing the compiled code for the **MATRIX** constructor is called **MATRIX.nrlib**. The `)nolibrary` option says that such files should not be created. The default is `)library`.

The `)vartrace` option causes the compiler to generate extra code for the constructor to support conditional tracing of variable assignments. Without this option, this code is suppressed and one cannot use the `)vars` option for the trace command.

The `)constructor` option is used to specify a particular constructor to compile. All other constructors in the file are ignored. The constructor name or abbreviation follows `)constructor`. Thus either

```
)compile matrix.spad )constructor RectangularMatrix
```

or

```
)compile matrix.spad )constructor RMATRIX
```

compiles the **RectangularMatrix** constructor defined in **matrix.spad**.

The `)break` and `)nobreak` options determine what the *spad* compiler does when it encounters an error. `)break` is the default and it indicates that processing should stop at the first error. The value of the `)set break` variable then controls what happens.

3.5 Operator Precedence Table Initialization

```
; PURPOSE: This file sets up properties which are used by the Boot lexical
```

```

;      analyzer for bottom-up recognition of operators. Also certain
;      other character-class definitions are included, as well as
;      table accessing functions.
;
; ORGANIZATION: Each section is organized in terms of Creation and Access code.
;
;      1. Led and Nud Tables
;      2. GLIPH Table
;      3. RENAMETOK Table
;      4. GENERIC Table
;      5. Character syntax class predicates

```

3.5.1 LED and NUD Tables

```

; **** 1. LED and NUD Tables

; ** TABLE PURPOSE

; Led and Nud have to do with operators. An operator with a Led property takes
; an operand on its left (infix/suffix operator).

; An operator with a Nud takes no operand on its left (prefix/nilfix).
; Some have both (e.g. - ). This terminology is from the Pratt parser.
; The translator for Scratchpad II is a modification of the Pratt parser which
; branches to special handlers when it is most convenient and practical to
; do so (Pratt's scheme cannot handle local contexts very easily).

; Both LEDs and NUDs have right and left binding powers. This is meaningful
; for prefix and infix operators. These powers are stored as the values of
; the LED and NUD properties of an atom, if the atom has such a property.
; The format is:

;      <Operator Left-Binding-Power Right-Binding-Power <Special-Handler>>

; where the Special-Handler is the name of a function to be evaluated when that
; keyword is encountered.

; The default values of Left and Right Binding-Power are NIL. NIL is a
; legitimate value signifying no precedence. If the Special-Handler is NIL,
; this is just an ordinary operator (as opposed to a surfix operator like
; if-then-else).
;
; The Nud value gives the precedence when the operator is a prefix op.
; The Led value gives the precedence when the operator is an infix op.
; Each op has 2 priorities, left and right.
; If the right priority of the first is greater than or equal to the
; left priority of the second then collect the second operator into
; the right argument of the first operator.

```

```

3.6 Glyph Table

Gliph is a symbol clump. The gliph property of a symbol gives the tree describing the tokens which begin with that symbol. The token reader uses the gliph property to determine the longest token. Thus `:=` is read as one token not as `:` followed by `=`.

— GLIPHTable —

```

(mapcar #'(lambda (x) (put (car x) 'gliph (cdr x)))
  '(
    ( \| (\))      )
    ( *  (*)       )
    ( \ ( (<) (\|) )
    ( +  (- (>))   )
    ( -  (>)       )
    ( <  (=) (<)   )
    ( /  (\/)      ) breaks */xxx
    ( \| (/)       )
    ( > (=) (>) (\))
    ( = (= (>)) (>) )
    ( \. (\.)      )
    ( ^ (=)        )
  )
)

```

```
( \~ (=)      )
( \: (=) (-) (\:)))
```

3.6.1 Rename Token Table

RENAMETOK defines alternate token strings which can be used for different keyboards which define equivalent tokens.

— RENAMETOKTable —

```
(mapcar
 #'(lambda (x) (put (car x) 'renametok (cadr x)) (makenewop x nil))
 '((\(\| \|) ; (| |) means []
   (\| \|)
   (\(< \|) ; (< >) means {}
   (>\ \|)))
```

3.6.2 Generic function table

GENERIC operators be suffixed by \$ qualifications in SPAD code. \$ is then followed by a domain label, such as I for Integer, which signifies which domain the operator refers to. For example `+$Integer` is `+` for Integers.

— GENERICTable —

```
(mapcar #'(lambda (x) (put x 'generic 'true))
 '(- = * |rem| |mod| |quo| |div| / ** |exquo| + - < > <= >= ^= ))
```

3.7 Giant steps, Baby steps

We will walk through the compiler with the EQ.spad example using a Giant-steps, Baby-steps approach. That is, we will show the large scale (Giant) transformations at each stage of compilation and discuss the details (Baby) in subsequent chapters.

Chapter 4

The Parser

4.1 EQ.spad

We will explain the compilation function using the file `EQ.spad`. We trace the execution of the various functions to understand the actual call parameters and results returned. The `EQ.spad` file is:

```
)abbrev domain EQ Equation

      z
      '(cons ,(car z) ,(newConstruct (cdr z)))))
```

4.3 preparse

The first large transformation of this input occurs in the function `preparse`. The `preparse` function reads the source file and breaks the input into a list of pairs. The first part of the pair is the line number of the input file and the second part of the pair is the actual source text as a string.

One feature that is the added semicolons at the end of the strings where the “pile” structure of the code has been converted to a semicolon delimited form.

4.3.1 defvar \$index

```
— initvars —
(defvar $index 0 "File line number of most recently read line")
```

4.3.2 defvar \$linelist

```
— initvars —
(defvar $linelist nil "Stack of preparsed lines")
```

4.3.3 defvar \$echolinestack

— initvars —
 (defvar \$echolinestack nil "Stack of lines to list")

4.3.4 defvar \$preparse-last-line

— initvars —
 (defvar \$preparse-last-line nil "Most recently read line")

4.4 Parsing routines

The **initialize-preparse** expects to be called before the **preparse** function. It initializes the state, in particular, it reads a single line from the input stream and stores it in **\$preparse-last-line**. The caller gives a stream and the **\$preparse-last-line** variable is initialized as:

```
2> (INITIALIZE-PREPARSE #<input stream "/tmp/EQ.spad">)
<2 (INITIALIZE-PREPARSE ")abbrev domain EQ Equation")
```

4.4.1 defun initialize-preparse

```
[initialize-preparse get-a-line (vol5)]
[$index p80]
[$linelist p80]
[$echolinestack p81]
[$preparse-last-line p81]
```

— defun initialize-preparse —

```
(defun initialize-preparse (strm)
  (setq $index 0)
  (setq $linelist nil)
  (setq $echolinestack nil)
  (setq $preparse-last-line (get-a-line strm)))
```

The **preparse** function returns a list of pairs of the form: ((linenumber . linestring) (linenumber . linestring)) For instance, for the file **EQ.spad**, we get:

```
2> (PREPARSE #<input stream "/tmp/EQ.spad">)
3> (PREPARSE1 (")abbrev domain EQ Equation"))
```

```

4> (|doSystemCommand| "abbrev domain EQ Equation")
<4 (|doSystemCommand| NIL)
<3 (PREPARSE1 ( ...[snip]... )

4.5.17 defun token-print[[\\$token p95](#)]

```

— defun token-print —
(defun token-print (token)
  (format out-stream "(token (symbol ~S) (type ~S))~%"
    (token-symbol token) (token-type token)))

```

4.5.18 Parsing reduction

4.5.19 destruct reduction

A reduction of a rule is any S-Expression the rule chooses to stack.

— **initvars** —

```
(destruct (reduction (:type list))
  (rule nil)           ; Name of rule
  (value nil))
```

Chapter 5

Parse Transformers

5.1 Direct called parse routines

5.1.1 defun parseTransform

[parseTran p99]
[\$defOp p??]

— defun parseTransform —

```
(defun |parseTransform| (x)
  (let (|$defOp|)
    (declare (special |$defOp|))
    (setq |$defOp| nil)
    (setq x (subst '$ '% x :test #'equal)) ; for new compiler compatibility
    (|parseTran| x)))
```

—————

5.1.2 defun parseTran

[parseAtom p100]
[parseConstruct p101]
[parseTran p99]
[parseTranList p101]
[getl p??]
[\$op p??]

— defun parseTran —

```
(defun |parseTran| (x)
  (labels (
    (g (op)
      (let (tmp1 tmp2 x)
        (seq
```

```

(if (and (consp op) (eq (qfirst op) '|elt|))
  (progn
    (setq tmp1 (qrest op))
    (and (consp tmp1)
      (progn
        (setq op (qfirst tmp1))
        (setq tmp2 (qrest tmp1))
        (and (consp tmp2)
          (eq (qrest tmp2) nil)
          (progn (setq x (qfirst tmp2)) t))))))
    (exit (g x)))
  (exit op))))
(let (|$op| arg1 u r fn)
  (declare (special |$op|))
  (setq |$op| nil)
  (if (atom x)
    (|parseAtom| x)
    (progn
      (setq |$op| (car x))
      (setq arg1 (cdr x))
      (setq u (g |$op|))
      (cond
        ((eq u '|construct|)
         (setq r (|parseConstruct| arg1))
         (if (and (consp |$op|) (eq (qfirst |$op|) '|elt|))
           (cons (|parseTran| |$op|) (cdr r))
           r))
        ((and (atom u) (setq fn (get1 u '|parseTran|))))
        (funcall fn arg1))
      (t (cons (|parseTran| |$op|) (|parseTranList| arg1)))))))

```

5.1.3 defun parseAtom

[parseLeave p¹²³]
 [\$NoValue p??]

— defun parseAtom —

```

(defun |parseAtom| (x)
  (declare (special |$NoValue|))
  (if (eq x '|break|)
    (|parseLeave| (list '|$NoValue|))
    x))

```

5.1.4 defun parseTranList

[parseTran p99]

[parseTranList p101]

— defun parseTranList —

```
(defun |parseTranList| (x)
  (if (atom x)
      (|parseTran| x)
      (cons (|parseTran| (car x)) (|parseTranList| (cdr x)))))
```

5.1.5 defplist parseConstruct

— postvars —

```
(eval-when (eval load)
  (setf (get '|construct| '|parseTran|) '|parseConstruct|))
```

5.1.6 defun parseConstruct

[parseTranList p101]

[\$insideConstructIfTrue p??]

— defun parseConstruct —

```
(defun |parseConstruct| (u)
  (let (|$insideConstructIfTrue| x)
    (declare (special |$insideConstructIfTrue|))
    (setf |$insideConstructIfTrue| t)
    (setf x (|parseTranList| u))
    (cons '|construct| x)))
```

5.2 Indirect called parse routines

In the **parseTran** function there is the code:

```
((and (atom u) (setf fn (get1 u '|parseTran|)))
  (funcall fn arg1))
```

The functions in this section are called through the symbol-plist of the symbol being parsed.
The original list read:

```
and      parseAnd
```

Chapter 6

Compile Transformers

With some specific exceptions most compile transformers are invoked through the property list item “`special`”. When a specific keyword is encountered in a list form the `compExpression` function looks up the keyword on the property list and funcalls the handler function, passing the form, the mode, and the environment.

If a handler for the keyword is not found then the `compForm` function is called to attempt to compile the form.

6.0.85 `defun compExpression`

```
[getl p??]  
[compForm p541]  
[$insideExpressionIfTrue p??]
```

— `defun compExpression` —

```
(defun |compExpression| (form mode env)  
  (let (|$insideExpressionIfTrue| fn)  
    (declare (special |$insideExpressionIfTrue|))  
    (setq |$insideExpressionIfTrue| t)  
    (if (and (atom (car form)) (setq fn (getl (car form) 'special)))  
        (funcall fn form mode env)  
        (|compForm| form mode env))))
```

The functions in this section are called through the symbol-plist of the symbol being parsed. In general, each of these functions takes 3 arguments

1. the **form** which is specific to the function
2. the **mode** a —Join—, which is a set of categories and domains
3. the **env** which is a list of functions and their modemaps

and the functions return modified versions of the three arguments suitable for further pro-

  "compDefineFunctor1" -> "compile"
  "compDefineLisplib" -> "compileDocumentation"
  "compileCases" -> "compile"
```

```

}

```

A Category is represented by a DEF form with 4 parts:

- a name
- a distnature
- an SC
- a body

For example, the BasicType category is written as

```

BasicType(): Category == with
  "=": (%,%) -> Boolean    ++ x=y tests if x and y are equal.
  "~=": (%,%) -> Boolean   ++ x~=y tests if x and y are not equal.
  add
    _~_(x:%,y:%) : Boolean == not(x=y)

```

Which compiles to the DEF form:

```

(DEF
  (|BasicType|)
  ((|Category|))
  (NIL)
  (|add|
    (CATEGORY |domain|
      (SIGNATURE = ((|Boolean|) $ $))
      (SIGNATURE ~= ((|Boolean|) $ $)))
    (CAPSULE
      (DEF
        (~= |x| |y|)
        ((|Boolean|) $ $)
        (NIL NIL NIL)
        (IF (= |x| |y|) |false| |true|))))))

```

6.1.1 defplist compDefine plist

We set up the `compDefine` function to handle the `DEF` keyword by setting the `special` keyword on the `DEF` symbol property list.

— postvars —

```
(eval-when (eval load)
  (setf (get 'def 'special) '|compDefine|))
```

6.1.2 defun compDefine

The `compDefine` function expects three arguments:

1. the **form** which is an `def` specifying the domain to define.
2. the **mode** a `—Join—`, which is a set of categories and domains
3. the **env** which is a list of functions and their `modemaps`

```
[compDefine1 p137]

6.1.19 defvar \$NoValueMode

— initvars —

```
(defvar |$NoValueMode| '|NoValueMode|)
```

6.1.20 defvar \$EmptyMode

\$EmptyMode is a constant whose value is \$EmptyMode. It is used by isPartialMode to decide if a modemap is partially constructed. If the \$EmptyMode constant occurs anywhere in the modemap structure at any depth then the modemap is still incomplete. To find this constant the isPartialMode function calls CONTAINED \$EmptyMode Y which will walk the structure Y looking for this constant.

      (t (cons (car z) (|optCONDtail| (cdr z)))))))
```

6.2.5 defvar `$BasicPredicates`

If these predicates are found in an expression the code optimizer routine `optPredicateIfTrue` then `optXLAM` will replace the call with the argument. This is used for predicates that test the type of their argument so that, for instance, a call to `integerp` on an integer will be replaced by that integer if it is true. This represents a simple kind of compile-time type evaluation.

   (t nil)))

```

6.2.9 Special case optimizers

Optimization functions are called through the OPTIMIZE property on the symbol property list. The current list is:

call	optCall
seq	optSEQ
eq	optEQ
minus	optMINUS
qsminus	optQSMINUS
-	opt-
lessp	optLESSP
spadcall	optSPADCALL
	optSuchthat
catch	optCatch
cond	optCond
mkRecord	optMkRecord
recordelt	optRECORDELT

```
setrecordelt optSETRECORDELT
recordcopy   optRECORDCOPY
```

Be aware that there are case-sensitivity issues. When found in the s-expression, each symbol in the left column will call a custom optimization routine in the right column. The optimization routines are below. Note that each routine has a special chunk in postvars using eval-when to set the property list at load time.

These optimizations are done destructively. That is, they modify the function in-place using rplac.

Not all of the optimization routines are called through the property list. Some are called only from other optimization routines, e.g. optPackageCall.

6.5 Indirect called comp routines

In the `compExpression` function there is the code:

```

(if (and (atom (car x)) (setq fn (get1 (car x) 'special)))
  (funcall fn x m e)
  (|compForm| x m e)))

```

6.5.1 defplist compAdd plist

We set up the `compAdd` function to handle the `add` keyword by setting the `special` keyword on the `add` symbol property list.

— postvars —

```

(eval-when (eval load)
  (setf (get '|add| 'special) 'compAdd))

```

6.5.2 defun compAdd

The compAdd function expects three arguments:

1. the **form** which is an —add— specifying the domain to extend and a set of functions to be added
2. the **mode** a —Join—, which is a set of categories and domains
3. the **env** which is a list of functions and their modemaps

The bulk of the work is performed by a call to compOrCroak which compiles the functions in the add form capsule.

The compAdd function returns a triple, the result of a call to compCapsule.

1. the **compiled capsule** which is a progn form which returns the domain
2. the **mode** from the input argument
3. the **env** prepended with the signatures of the functions in the body of the add.

6.5.8 defun compCapsuleItems

The variable `data` appears to be unbound at runtime. Optimized code won't check for this but interpreted code fails. We should PROVE that `data` is unbound at runtime but have not done so yet. Rather than remove the code entirely (since there MIGHT be a path where it is used) we check for the runtime bound case and assign `$myFunctorBody` if `data` has a value.

The `compCapsuleInner` function in this file LOOKS like it sets `data` and expects code to manipulate the assigned `data` structure. Since we can't be sure we take the least disruptive course of action.

6.5.13 defplist compCase plist

We set up the `compCase` function to handle the `case` keyword by setting the `special` keyword on the `case` symbol property list.

— postvars —

```

(eval-when (eval load)
  (setf (get '|case| 'special) '|compCase|))

```

6.5.14 defun compCase

Will the jerk who commented out these two functions please NOT do so again. These functions ARE needed, and case can NOT be done by modemap alone. The reason is that A case B requires to take A evaluated, but B unevaluated. Therefore a special function is required. You may have thought that you had tested this on “failed” etc., but “failed” evaluates to it’s own mode. Try it on x case \$ next time.

7.2 Indirect called postparse routines

In the `postTran` function there is the code:

```

((and (atom op) (setq f (getl op '|postTran|)))
 (funcall f x))

```

The functions in this section are called through the symbol-plist of the symbol being parsed. The original list read:

add	postAdd	
@	postAtSign	
:BF:	postBigFloat	
Block	postBlock	
CATEGORY	postCategory	
COLLECT	postCollect	
:	postColon	
::	postColonColon	
,	postComma	
construct	postConstruct	
==	postDef	
=>	postExit	
if	postIf	
in	postin	;" the infix operator version of in"
IN	postIn	;" the iterator form of in"
Join	postJoin	
->	postMapping	
==>	postMDef	
pretend	postPretend	
QUOTE	postQUOTE	
Reduce	postReduce	
REPEAT	postRepeat	
Scripts	postScripts	
;	postSemiColon	
Signature	postSignature	
/	postSlash	
@Tuple	postTuple	
TupleCollect	postTupleCollect	
where	postWhere	
with	postWith

8.1.68 The PARSE implicit routines

These symbols are not explicitly referenced in the source. Nevertheless, they are called during runtime. For example, PARSE-SemiColon is called in the chain:

```
PARSE-Enclosure {loc0=nil,loc1="(V ==> Vector; " } [ihs=35]
  PARSE-Expr
    PARSE-LedPart
      PARSE-Operation
        PARSE-getSemanticForm
          PARSE-SemiColon
```

so there is a bit of indirection involved in the call.

8.1.69 defun PARSE-Suffix

```
[push-reduction p421]

8.2 The PARSE support routines

This section is broken up into 3 levels:

- String grabbing: Match String, Match Advance String
- Token handling: Current Token, Next Token, Advance Token
- Character handling: Current Char, Next Char, Advance Char
- Line handling: Next Line, Print Next Line
- Error Handling

- Floating Point Support
- Dollar Translation

8.2.1 String grabbing

String grabbing is the art of matching initial segments of the current line, and removing them from the line before the get tokenized if they match (or removing the corresponding current tokens).

8.2.2 defun match-string

The match-string function returns length of X if X matches initial segment of inputstream.

[unget-tokens p412]
 [skip-blanks p408]
 [match-string line-past-end-p (vol5)]
 [match-string current-line (vol5)]

—————

8.2.37 Applying metagrammatical elements of a production (e.g., Star).

- **must** means that if it is not present in the token stream, it is a syntax error.
- **optional** means that if it is present in the token stream, that is a good thing, otherwise don't worry (like [foo] in BNF notation).
- **action** is something we do as a consequence of successful parsing; it is inserted at the end of the conjunction of requirements for a successful parse, and so should return T.

- **sequence** consists of a head, which if recognized implies that the tail must follow. Following tail are actions, which are performed upon recognizing the head and tail.

8.2.38 defmacro Bang

If the execution of prod does not result in an increase in the size of the stack, then stack a NIL. Return the value of prod.

— **defmacro bang** —

```
(defmacro bang (lab prod)

Chapter 14

The Compiler

14.0.57 defvar \$newConlist

A list of new constructors discovered during compile. These are used in a call to `extendLocalLibdb` when a user compiles new local code.

— **initvars** —

```
(defvar |$newConlist| nil
  "A list of new constructors discovered during compile ")
```

14.1 Compiling EQ.spad

Given the top level command:

```
)co EQ
```

The default call chain looks like:

```
1> (|compiler| ...)
2> (|compileSpad2Cmd| ...)
   Compiling AXIOM source code from file /tmp/A.spad
3> (|compilerDoit| ...)
4> (|/RQ,LIB|)
5> (/RF-1 ...)
6> (SPAD ...)
   AXSERV abbreviates package AxiomServer
7> (S-PROCESS ...)
8> (|compTopLevel| ...)
9> (|compOrCroak| ...)
10> (|compOrCroak1| ...)
11> (|comp| ...)
12> (|compNoStacking| ...)
13> (|comp2| ...)
14> (|comp3| ...)
15> (|compExpression| ...)
```

```

*
16> (|compWhere| ...)
17> (|comp| ...)
18> (|compNoStacking| ...)
19> (|comp2| ...)
20> (|comp3| ...)
21> (|compExpression| ...)
22> (|compSeq| ...)
23> (|compSeq1| ...)
24> (|compSeqItem| ...)
25> (|comp| ...)
26> (|compNoStacking| ...)
27> (|comp2| ...)
28> (|comp3| ...)
29> (|compExpression| ...)
<29 (|compExpression| ...)
<28 (|comp3| ...)

<26 (|compColon| ...)

```

```

<25 (|comp3| ...)
<24 (|comp2| ...)
<23 (|compNoStacking| ...)
<22 (|comp| ...)

```

In order to explain the compiler we will walk through the compilation of EQ.spad, which handles equations as mathematical objects. We start the system. Most of the structure in Axiom are circular so we have to the `*print-cycle*` to true.

```
root@spiff:/tmp# axiom -nox
```

```
(1) -> )lisp (setq *print-circle* t)
```

```
Value = T
```

We trace the function we find interesting:

```
(1) -> )lisp (trace |compiler|)
```

```
Value = (|compiler|)
```

14.2 The top level compiler command

This is the graph of the functions used for compDefine. The syntax is a graphviz dot file. To generate this graph as a JPEG file, type:

```
tangle v9compDefine.dot bookvol9.pamphlet >v9compdefine.dot
dot -Tjpg v9compiler.dot >v9compiler.jpg
```

— v9compiler.dot —

```

→

14.2.1 defun compiler

We compile the spad file. We can see that the **compiler** function gets a list

```
(1) -> )co EQ
```

```
1> (|compiler| (EQ))
```

In order to find this file, the **pathname** and **pathnameType** functions are used to find the location and pathname to the file. They **pathnameType** function eventually returns the fact that this is a **spad** source file. Once that is known we call the **compileSpad2Cmd** function with a list containing the full pathname as a string.

```

1> (|compiler| (EQ))
2> (|pathname| (EQ))
<2 (|pathname| #p"EQ")
2> (|pathnameType| #p"EQ")
3> (|pathname| #p"EQ")
<3 (|pathname| #p"EQ")
<2 (|pathnameType| NIL)
2> (|pathnameType| "/tmp/EQ.spad")
3> (|pathname| "/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|pathnameType| "/tmp/EQ.spad")
3> (|pathname| "/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|pathnameType| "/tmp/EQ.spad")
3> (|pathname| "/tmp/EQ.spad")
<3 (|pathname| #p"/tmp/EQ.spad")
<2 (|pathnameType| "spad")
2> (|compileSpad2Cmd| ("/tmp/EQ.spad"))

            nil))))))))))))))

```

14.2.2 defun compileSpad2Cmd

This function sets up a constructor name (or nil if the whole file is to be compiled) and a set of options for the next layer of compile commands. For example, the call

```
(co dh )constructor DHMATRIX )functions identity
```

will look for the file `dh.spad` and issue a call

```
(|compilerDoitWithScreenedLisplib| (|DenavitHartenbergMatrix|) (|c| |lib|))
```

The argument to this function, as noted above, is a list containing the string pathname to the file.

```
2> (|compileSpad2Cmd| ("/tmp/EQ.spad"))
```

Again we find a lot of redundant work. We finally end up calling **compilerDoit** with a constructed argument list:

```
2> (|compilerDoit| NIL (|rq| |lib|))
[compileSpad2Cmd pathname (vol5)]
[compileSpad2Cmd pathnameType (vol5)]
[compileSpad2Cmd namestring (vol5)]

(defun /RQ,LIB (&rest foo &aux (echo-meta nil) ($lisplib t))
  (declare (special echo-meta $lisplib) (ignore foo))
  (/rf-1 nil))

```

14.2.9 defun /rf-1

Since this function is called with nil we fall directly into the call to the function **spad**:

```

(2) -> )co EQ
      Compiling AXIOM source code from file /tmp/EQ.spad using old system
      compiler.
1> (|compilerDoit| NIL (|rq| |lib|))
2> (|/RQ,LIB|)
3> (/RF-1 NIL)
4> (SPAD "/tmp/EQ.spad")
...[snip]...
      <4 (SPAD T)
      <3 (/RF-1 T)
      <2 (|/RQ,LIB| T)
      <1 (|compilerDoit| T)
[/rf-1 makeInputFilename (vol5)]
[ncINTERPFILE p563]
calls/rf-1spad [/editfile p??]
[echo-meta p??]

```

```

— defun /rf-1 —
(defun /rf-1 (ignore)
  (declare (ignore ignore))
  (let* ((input-file (makeInputFilename /editfile))
        (type (pathname-type input-file)))
    (declare (special echo-meta /editfile))
    (cond
      ((string= type "lisp") (load input-file))
      ((string= type "input") (|ncINTERPFILE| input-file echo-meta))
      (t (spad input-file)))))

```

14.2.10 defun spad

Here we begin the actual compilation process.

```

1> (SPAD "/tmp/EQ.spad")

```

The major steps in this process involve the **preparse** function. (See book volume 5 for more details). The **preparse** function returns a list of pairs of the form: ((linenumber . linestring) (linenumber . linestring)) For instance, for the file `EQ.spad`, we get:

```

<2 (PREPARSE (
(19 . "Equation(S: Type): public == private where")

```

```

(20 . " (Ex ==> OutputForm;")
(21 . "   public ==> Type with")
(22 . "   (\="\": (S, S) -> $;")
...[skip]...
(202 . "       inv eq == [inv lhs eq, inv rhs eq]);")
(203 . "       if S has ExpressionSpace then")
(204 . "       subst(eq1,eq2) ==")
(205 . "       (eq3 := eq2 pretend Equation S;")
(206 . "       [subst(lhs eq1,eq3),subst(rhs eq1,eq3)])))))

```

```

```

Given:

CohenCategory(): Category == SetCategory with

```

kind: (CExpr) -> Boolean
operand: (CExpr, Integer) -> CExpr
numberOfOperand: (CExpr) -> Integer
construct: (CExpr, CExpr) -> CExpr

```

the resulting call looks like:

```

(|compOrCroak|
 (DEF (|CohenCategory|)
  ((|Category|)
   (NIL)
   (|Join|
    (|SetCategory|
     (CATEGORY |package|
      (SIGNATURE |kind| ((|Boolean|) |CExpr|))
      (SIGNATURE |operand| (|CExpr| |CExpr| (|Integer|)))
      (SIGNATURE |numberOfOperand| ((|Integer|) |CExpr|))
      (SIGNATURE |construct| (|CExpr| |CExpr| |CExpr|))))))
  |$EmptyMode|
  (((
   (|$DomainsInScope|
    (FLUID . |true|)
    (special |$EmptyMode| |$NoValueMode|)))))))

```

This compiler call expects the first argument *x* to be a DEF form to compile, The second argument, *m*, is the mode. The third argument, *e*, is the environment.

14.2.15 defun compOrCroak

[compOrCroak1 p529]

— defun compOrCroak —

```

(defun |compOrCroak| (form mode env)
  (|compOrCroak1| form mode env nil nil))

```

This results in a call to the inner function with

```

(|compOrCroak1|

```

```

(DEF (|CohenCategory|)
  ((|Category|)
   (NIL)
   (|Join|
    (|SetCategory|)
    (CATEGORY |package|
     (SIGNATURE |kind| ((|Boolean|) |CEpr|))
     (SIGNATURE |operand| (|CEpr| |CEpr| (|Integer|)))
     (SIGNATURE |numberOfOperand| ((|Integer|) |CEpr|))
     (SIGNATURE |construct| (|CEpr| |CEpr| |CEpr|))))
  |$EmptyModel|
  (((
   |$DomainsInScope|
   (FLUID . |true|)
   (special |$EmptyModel| |$NoValueModel|))))
  NIL
  NIL
  |comp|)

```

The inner function augments the environment with information from the compiler stack `$compStack` and `$compErrorMessageStack`. Note that these variables are passed in the argument list so they get preserved on the call stack. The calling function gets called for every inner form so we use this implicit stacking to retain the information.

Abstract: This paper presents an ongoing effort to integrate the Axiom family of computer algebra systems with Poly/ML-based proof assistants in the same framework. A long term goal is to make a large set of efficient implementations of algebraic algorithms available to popular proof assistants, and also to bring the power of mechanized formal verification to a family of strongly typed computer algebra systems at a modest cost. Our approach is based on retargeting the code generator of the OpenAxiom compiler to the Poly/ML abstract machine.

Abstract: Reusing code from software libraries can reduce the time and effort to construct software systems and also enable the development of larger systems. However, the benefits that come from the use of software libraries may not be realized due to limitations in the

way that traditional software libraries are constructed. Libraries come equipped with application programming interfaces (API) that help enforce the correct use of the abstraction in those libraries. Writing new components and adapting existing ones to conform to library APIs may require substantial amounts of “glue” code that potentially affects software’s efficiency, robustness, and ease-of-maintenance. If, as a result, the idea of reusing functionality from a software library is rejected, no benefits of reuse will be realized. This dissertation explores and develops techniques that support the construction of software libraries with abstraction layers that do not impede efficiency. In many situations, glue code can be expected to have very low (or zero) performance overhead. In particular, we describe advances in the design and development of active libraries – software libraries that take an active role in the compilation of the user’s code. Common to the presented techniques is that they may “break” a library API (in a controlled manner) to adapt the functionality of the library for a particular use case. The concrete contributions of this dissertation are: a library API that supports iterator selection in the Standard Template Library, allowing generic algorithms to find the most suitable traversal through a container, allowing (in one case) a 30-fold improvement in performance; the development of techniques, idioms, and best practices for `concepts` and `concept_maps` in C++, allowing the construction of algorithms for one domain entirely in terms of formalisms from a second domain; the construction of generic algorithms for algorithmic differentiation, implemented as an active library in Spad, language of the Open Axiom computer algebra system, allowing algorithmic differentiation to be applied to the appropriate mathematical object and not just concrete data-types; and the description of a static analysis framework to describe the generic programming notion of local specialization with Spad, allowing more sophisticated (value-based) control over algorithm selection and specialization in categories and domains. We will find that active libraries simultaneously increase the expressivity of the underlying language and the performance of software using those libraries
